1 **Abstract**

2 Surfactant dry solution (DS) was prepared by mixing sodium dodecyl sulfate (SDS)  
3 solution, hydrophobic silica nanoparticles and air in a high speed blender. Flour-like SDS-DS  
4 combines the advantages of dispersed dry water and active SDS solution. Methane storage in  
5 clathrate hydrates using SDS-DS was investigated in a stainless steel vessel without stirring  
6 under the condition of 5.0 MPa and 273.2 K. The results demonstrated that highly dispersed  
7 SDS-DS could significantly enhance formation kinetics and storage capacity of methane  
8 hydrate. SDS-DS exhibited about the same methane storage capacity ( $172.96 \text{ m}^3 \cdot \text{m}^{-3}$ ) as dry  
9 water, but faster storage rates than dry water. Compared to SDS solution, SDS-DS had similar  
10 storage rates ( $7.44 \text{ m}^3 \cdot \text{m}^{-3} \cdot \text{min}^{-1}$ ) and higher methane storage capacity under the relative low  
11 pressure. However, the aggregation of partial SDS-DS powders destroyed its original  
12 dispersive property after hydrate dissociation.

13 *Keywords:* surfactant, dry solution, methane hydrate, formation kinetics

## 1 **1. Introduction**

2 Gas hydrates are crystalline compounds encaging noble gases or short chain hydrocarbons  
3 as guest molecules in a hydrogen-bonded water framework (Sloan and Koh, 2008). In recent  
4 years, natural gas hydrates have drawn significant attention not only as a new natural energy  
5 resource but also as a new economical medium for natural gas storage and transportation  
6 (Sloan, 2003; Englezos and Lee, 2005; Koh and Sloan, 2007). One standard volume of such  
7 hydrates can stably store about 180 standard volumes of natural gas (Sloan and Koh, 2008),  
8 which corresponds to approximately one-quarter energy density of liquefied natural gas. High  
9 storage capacity of hydrate have also contributed carbon dioxide capture (Linga et al., 2007),  
10 flue gas separation (Kang and Lee, 2000; Fan et al., 2009), hydrogen storage (Mao et al., 2002;  
11 Struzhkin et al., 2007), seawater desalination (Park et al., 2011) and solute purification (Yoon  
12 and Lee, 1997) in the form of hydrate.

13 However, the application on an industrial scale has been critically challenged by slow  
14 formation rate and low conversion ratio of gas to hydrate resulting in insufficient storage  
15 capacity. The causes of these problems lie in inadequate gas-water contacts and unreacted  
16 interstitial water trapped in the hydrate mass, neither of which favors hydrate nucleation and  
17 growth. Therefore, enhancing gas-water contacts is crucial for efficient hydration of gas to  
18 solid.

19 Mechanical methods, such as liquid stirring (Englezos et al., 1987; Hao et al., 2007), gas  
20 bubbling (Maini and Bishnoi, 1981; Luo et al., 2007), liquid spraying (Fukumoto et al., 2001;  
21 Ohmura et al., 2002), are often employed in experimental operations to increase the formation  
22 rate of gas hydrates. However, the substantial cost of mechanical mixing devices and energy

1 requirements may be unfeasible in real gas storage application. The addition of surfactants to  
2 water can enhance gas hydrates formation without mechanical perturbation (Zhong and  
3 Rogers, 2000; Link et al., 2003; Zhang et al., 2007). Evidently, the presence of surfactants  
4 increases gas-water contacts by changing the hydrate morphology (Yoslim et al., 2010), but  
5 the gas storage medium remains a pool of stationary liquid. Silica sand saturated with water  
6 (fixed bed column) is recently employed for enhancing the rate of gas hydrate formation and  
7 the percent of water conversion to hydrate (Linga et al., 2007). However, the volume  
8 “penalty” is high because the sand occupies quite large space in the bed column. Grinding ice  
9 powder exposed in the gas provides considerable gas-ice contacts and increases hydrate  
10 formation rates (Staykova et al., 2003), but the material must be prepared laboriously without  
11 melting. Dispersed liquid such as dry water (DW) with higher specific surface than ice  
12 powder, is used to dramatically enhance the methane uptake rate in hydrates under static  
13 conditions (Wang et al., 2008; Carter et al., 2010). Dry water can capture more methane than  
14 surfactant solution, but the enhanced rate of gas uptake is slightly inferior to the rate increased  
15 by surfactant (Carter et al., 2010).

16 Considering storage advantages of DW and surfactant solution, in this work, we attempt to  
17 prepare a surfactant dry solution (DS) using sodium dodecyl sulfate (SDS) solution and  
18 hydrophobic silica nanoparticles. Formation kinetic behaviors of methane hydrate in the  
19 SDS-DS were investigated under given pressure and temperature. In order to distinctly  
20 observe the effect of SDS-DS on hydration kinetics, DW and SDS solution also were used for  
21 methane hydrate formation under the same operating conditions, respectively. The results are  
22 expected to provide useful information on kinetic properties of hydrate formation in static

1 dispersed solution.

## 2 **2. Experimental**

### 3 *2.1 Preparation of surfactant dry solution*

4 Full details of the procedure for preparation of dry liquid can be referred elsewhere (Binks  
5 and Murakami, 2006). A sample of hydrophobic silica nanoparticles (HB630) with particle  
6 size range of 5~15 nm was supplied by Guangzhou GBS High-Tech & Industry Co., Ltd.. A  
7 sample of sodium dodecyl sulfate (SDS) with certified purity of >99% was purchased from  
8 Shanghai Bio Science & Technology Co., Ltd.. To prepare SDS-DS, SDS (0.03 g) was  
9 dissolved in deionized water (99.97 g) to form SDS solution beforehand. And then the  
10 solution was poured into a blender (Philips HR1727/06, 1.5 liter) and silica HB630 was added  
11 to the solution. Mixing was carried out at a speed of 18000 rpm for two 15 seconds under  
12 ambient conditions. SDS-DS sample looks like dry flour but can freely flow like liquid. Four  
13 mixing ratios of solution to silica were designed, as shown in Table 1. DW was also prepared  
14 by mixing 46.25 g of deionized water and 3.75 g of HB630 with the same operation above.

### 15 *2.2 Formation of methane hydrate*

16 Gas consumption based on pressure-volume-temperature (PVT) measurements can be  
17 considered as an efficient method to conduct laboratory experiments, which was reported in  
18 our previous paper (Yang et al., 2012). The apparatus employed in this work is shown  
19 schematically in Fig. 1. Before each experiment, a stainless steel high-pressure vessel (50 mm  
20 in diameter, 153 mm in height and effective volume of 300 cm<sup>3</sup>, Jiangsu Hai'an Scientific  
21 Research Instrument Factory) was washed with deionized water and loaded with 15.00 g of  
22 SDS-DS (or DW or SDS solution or bulk water). Subsequently, a vacuum pump (2XZ-4,

1 Zhejiang Taizhou Qiuqing Vacuum pump Co., Ltd.) was started to evacuate air from the  
2 apparatus, and then the vessel was flushed with methane (99.99 % purity, Guangzhou Yinglai  
3 Gases Co., Ltd) three times to ensure the absence of air. Afterwards, a circulating coolant bath  
4 (THD-3010, Zhejiang Ningbo Tianheng Instrument Factory) with a heating/cooling coil was  
5 turned on to control the vessel temperature to 273.2 K. The coolant with a freezing point  
6 lower than 243 K is prepared by blending equivalent volume of water and glycol. Two  
7 thermal resistance detectors (Pt100,  $\pm 0.01$  K, -30~200 °C Jiangsu Plaza Premium Electric  
8 Instrument Co., Ltd.) were used for measuring the temperatures of gas phase and liquid phase,  
9 respectively. Once the desired temperature was maintained constant for several minutes,  
10 methane was injected into the vessel until the given pressure (5.0 MPa) was reached, and then  
11 gas injection was cut off. The pressure of gas supply was monitored using a pressure gauge  
12 with a precision of  $\pm 0.1$  MPa. A pressure transducer (DG1300,  $\pm 0.01$  MPa, 0~40 MPa,  
13 Guangzhou Senex Instrument Co., Ltd.) was used for measuring the pressure in the vessel.  
14 The time, temperature and pressure information was collected (10 seconds between individual  
15  $t$ - $T$ - $P$  points) by Agilent 34970A Data Logger (Agilent Technologies Co., Ltd.) and displayed  
16 on the computer screen. In the initial period of hydrate formation, liquid temperature  
17 increased while the gas pressure decreased obviously. When the pressure drop rate was less  
18 than 0.01 MPa over 30 min, hydration process was assumed to reach its destination.  
19 Experimental conditions of all tests conducted were listed in Table 2.

### 20 *2.3 Calculation of methane storage rate and capacity*

21 Methane storage rate and capacity during the hydration process could be determined from  
22 the  $t$ - $T$ - $P$  data. The formation rate,  $F$ , was defined as

$$F = \frac{d(V_{t,\text{gas}}^h)_{\text{STP}}}{V_t^h dt} \approx \frac{(\Delta V_{t,\text{gas}}^h)_{\text{STP}}}{V_t^h \Delta t}, \quad (1)$$

where  $V^h$ ,  $V_{\text{gas}}^h$  and  $\Delta V_{\text{gas}}^h$  are the accumulative volume of hydrate phase, the volume of gas in hydrate phase and the volume increment of gas in hydrate phase in the period of  $\Delta t$ , respectively. The subscript  $t$ , as well as 0,  $t + \Delta t$  and e appeared in the following equations denote the state of time  $t$ , the initial state, the state of time  $t + \Delta t$  and the final (equilibrium) state, respectively. STP represents the standard temperature and pressure.

Zhang et al. (2005) stated that the water expands to about 1.25 times its original volume during its conversion into hydrate. Therefore,  $V_t^h$  is determined by the following equation:

$$V_t^h = 1.25\alpha_t V_0^l, \quad (2)$$

where  $V_0^l$  is the initial volume of liquid phase in the vessel and  $\alpha$  is the fraction of water converted into hydrate, it is evaluated with the following equation:

$$\alpha_t = \frac{(V_{t,\text{gas}}^h)_{\text{STP}}}{(V_{\text{e,gas}}^h)_{\text{STP}}}, \quad (3)$$

where  $(V_{t,\text{gas}}^h)_{\text{STP}}$  and  $(V_{\text{e,gas}}^h)_{\text{STP}}$  are described by the following formulas in the unit of  $\text{cm}^3$ :

$$(V_{t,\text{gas}}^h)_{\text{STP}} = 22400n_{t,\text{gas}}^h, \quad (V_{\text{e,gas}}^h)_{\text{STP}} = 22400n_{\text{e,gas}}^h, \quad (4)$$

where  $n_{\text{gas}}^h$  is the molar number of gas in hydrate phase or the molar number of gas uptake during hydrate formation.

The idea unit cell formula of structure I is  $2(5^{12}) \cdot 6(5^{12}6^2) \cdot 46\text{H}_2\text{O}$  (Sloan and Koh, 2008).

When the unit of water volume is  $\text{cm}^3$ , the mass value of water equals to its volume value. So according to the formula of structure I,  $n_{\text{e,gas}}^h$  can be determined by:

$$n_{\text{e,gas}}^h = \frac{V_0^l}{18 \times 46} (2\theta_1 + 6\theta_2), \quad (5)$$

where  $\theta_1$  and  $\theta_2$  are the occupancy of gas molecules in small cavities and large cavities of

1 hydrate, respectively. The model of Chen and Guo is used to determine  $\theta_1$  and  $\theta_2$  (Chen  
2 and Guo, 1998).

3 The standard volume increment of gas in hydrate phase,  $(\Delta V_{t,\text{gas}}^h)_{\text{STP}}$ , can be calculated by  
4 the following equations in the unit of  $\text{cm}^3$ :

$$5 \quad (\Delta V_{t,\text{gas}}^h)_{\text{STP}} = 22400(n_{t+\Delta t,\text{gas}}^h - n_{t,\text{gas}}^h), \quad (6)$$

$$6 \quad n_{t,\text{gas}}^h = n_0^g - n_t^g, \quad n_{t+\Delta t,\text{gas}}^h = n_0^g - n_{t+\Delta t}^g, \quad (7)$$

7 where  $n_{\text{gas}}^h$  and  $n^g$  represents the molar number of gas in hydrate phase and the molar  
8 number of gas phase, respectively.  $n_0^g$ ,  $n_t^g$  and  $n_{t+\Delta t}^g$  can be determined by:

$$9 \quad n_0^g = \frac{P_0 V_0^g}{Z_0 R T_0}, \quad n_t^g = \frac{P_t V_t^g}{Z_t R T_t}, \quad n_{t+\Delta t}^g = \frac{P_{t+\Delta t} V_{t+\Delta t}^g}{Z_{t+\Delta t} R T_{t+\Delta t}}, \quad (8)$$

10 where  $P$ ,  $T$ ,  $V^g$  and  $Z$  are the pressure, the temperature, the volume of gas phase and the gas  
11 compressibility factor, respectively. The compressibility factor  $Z$  is calculated with  
12 Redlich-Kwong equation (Redlich and Kwong, 1949).  $V_0^g$  can be described by:

$$13 \quad V_0^g = V_{\text{vessel}} - V_0^l - V^{\text{Si}}, \quad (9)$$

14 where  $V_{\text{vessel}}$  is the volume of the pressure vessel and  $V^{\text{Si}}$  is the volume of solid silica  
15 particles.  $V^{\text{Si}}$  can be calculated indirectly by the mass of silica HB630 and its density of 2.2  
16  $\text{g}\cdot\text{cm}^{-3}$ . In view of the volume expansion of solution and the constant volume of pressure  
17 vessel, the increasing volume of the condensed phase (liquid and hydrate) will occupy the gas  
18 phase space. It leads to the decrease of the gas phase volume correspondingly. So the volume  
19 of gas phase,  $V_0^g$ , should be corrected by:

$$20 \quad V_t^g = V_0^g - 0.25\alpha_t V_0^l, \quad V_{t+\Delta t}^g = V_0^g - 0.25\alpha_{t+\Delta t} V_0^l, \quad (10)$$

21 where  $\alpha$  is calculated by Eq. (3) and Eq. (4).

1 The storage capacity,  $C$ , can be obtained conveniently with the equation of  $C = \frac{(V_{t,\text{gas}}^h)_{\text{STP}}}{V_t^h}$

2 together with above equations.

### 3 **3. Results and discussion**

#### 4 *3.1 Surfactant dry solution preparation and morphology*

5 SDD-DS is solution droplets-in-air inverse foam formed by mixing SDS solution,  
6 hydrophobic silica nanoparticles and air in a high speed blender. Fig. 2 illustrates  
7 schematically the transition from bulk solution to micro-droplets in the presence of silica  
8 particles. Hydrophobic silica particles can encapsulate isolated macroscopic SDS solution  
9 droplets in air. Highly dispersed SDS-DS droplets are like solid flour powder (upper right in  
10 Fig. 2), but its water content is more than 90 wt%. The bulk density of SDS-DS was measured  
11 to be about  $0.55\sim 0.60 \text{ g}\cdot\text{cm}^{-3}$ . Not only SDS-DS droplets can provide plenty of gas-liquid  
12 contacts, but also each droplet encapsulated by HB630 can be considered as a micro hydration  
13 system containing surfactant. Therefore, SDS-DS is expected to have better enhanced effects  
14 on hydrate formation than single DW or single SDS solution. Additionally, the SDS-DS has  
15 high stability and its good dispersive property can be maintained for around 6 months at room  
16 temperature.

17 The morphology of SDS-DS droplets with altered silica contents can be distinguished in an  
18 inverted optical microscope (Carl Zeiss Axio Observer A1) with an accuracy of  $1 \mu\text{m}$ .  
19 Photographs were taken with a digital camera (IMAGING Micro-Publisher 5.0RTV). The  
20 particle size of SDS-DS droplets was measured using an attendant graphics-software of the  
21 optical microscope. The sample with 7.5 wt% silica particles (Fig. 3c) had uniform particle  
22 size, narrow size range ( $1\sim 2 \mu\text{m}$ ) and ample specific surface. Solution droplets with similar

1 particle size existed in the sample with 10.0 wt% silica particles (Fig. 3d), but excess fumed  
2 silica particles were intermixed with droplets. By comparison, the particle size of sample with  
3 5.0 wt% fumed silica particles (Fig. 3b) was nonuniform and ranged from 3 $\mu$ m to 10  $\mu$ m. The  
4 sample with 2.5 wt% fumed silica particles (Fig. 3a) exhibited very poor dispersion, such as  
5 irregular shape and large droplet size with the range of 15~120  $\mu$ m. Excess solution resulted  
6 in large droplets due to coalescence. The particle size of SDS-DS droplets with above four  
7 silica contents is shown in Fig. 4.

### 8 *3.2 Methane hydrate formation*

9 For all the SDS-DS systems in the work, every pressure curves and temperature curves  
10 exhibit similar changes. Take SDS-DS system (7.5 wt% silica HB630) for an example, typical  
11 variations of gas pressure and liquid temperature with time for hydration systems of bulk  
12 water and SDS-DS are shown in Fig. 5. The vessel was pressurized to 5.0 MPa at the  
13 temperature of 273.2 K. In the bulk water system, there was no clear evidence (pressure drop  
14 and temperature rise) that methane hydrate was formed under the conditions. By contrast,  
15 when the dispersed SDS-DS was employed, dramatic methane pressure drop together with  
16 SDS-DS temperature rise occurred at an induction time of 8.2 min. It was an indication of the  
17 start of methane hydrate formation and a solid hydrate layer was formed at gas-droplet  
18 interface. As the hydrate grew, the pressure gradually decreased, meanwhile the temperature  
19 increased rapidly to a maximum and then decreased to the initial temperature. When the  
20 hydrate layer developed to a thick wall on the surface of SDS-DS droplets, there was no  
21 hydrate formation and methane pressure stopped decrease. The rapid gas consumed in  
22 SDS-DS can compete with (even surpass) that reported for methane enclathration in dry water

1 under 8.6 MPa (Wang et al., 2008) which is higher than our test pressure. The behavior may  
2 be attributed to the highly dispersed SDS solution which provides sufficient gas-liquid contact  
3 area during hydrate nucleation and growth.

### 4 *3.3 Methane storage rate and capacity*

5 Kinetics of methane uptake in SDS-DS samples with altered contents of silica HB630  
6 under 5.0 MPa and 273.2 K is described in Fig. 6. Methane uptake in the bulk water only  
7 approached to about  $7.0 \text{ m}^3 \cdot \text{m}^{-3}$  during the whole experimental process. Few contacts of water  
8 molecules and methane molecules should be the main cause of little hydration. However,  
9 there are drastic increase gas consumptions in all the SDS-DS systems (2.5 wt%~10.0 wt%  
10 HB630). At the beginning of 40 min, the curves of methane uptakes nearly close to straight  
11 lines with about the same slope for these SDS-DS systems. Gas storage capacities reach their  
12 maximum values (more than  $150 \text{ m}^3 \cdot \text{m}^{-3}$ ) within about 100 min. Methane uptake rates, slopes  
13 of capacity curves, are shown in the inner plots of Fig. 6. Methane hydration rate in the bulk  
14 water system nearly approached to 0, while in SDS-DS systems all hydration rates increase  
15 their maximum (more than  $7.0 \text{ m}^3 \cdot \text{m}^{-3} \cdot \text{min}^{-1}$ ) and then tend to 0. The maximum capacity and  
16 rate for each system are listed in Table 2. The silica HB630 contents (or droplets size) of  
17 SDS-DS has no obvious effects on the kinetics of methane uptake, but the methane storage  
18 capacity of the sample with 7.5 wt% silica particles was superior to that of other DS samples.  
19 The SDS-DS sample with the highest capacity exhibits better dispersion (smaller particle size,  
20 less free fumed silica particles and less free liquid water) than other samples, which is stated  
21 in Fig. 3. The large specific surface and active droplets of SDS-DS significantly contribute to  
22 the enhancement of rate and capacity.

1 Fig. 7 shows the comparison of methane uptake kinetics in SDS solution, DW and SDS-DS  
2 (7.5 wt% silica) under the initial pressure of 5.0 MPa ( $T = 273.2$  K). The bulk solution had the  
3 same concentration of SDS as the solution used for preparing SDS-DS. The DW kept  
4 identical with the silica content of the SDS-DS. These three systems all greatly increased the  
5 formation rate and storage capacity of hydrate compared to the bulk water system in Fig. 6.  
6 The use of SDS solution can increase gas-water contacts by changing hydrate morphology  
7 and enhance methane uptake kinetics (Yoslim et al., 2010). The dispersed DW also provided  
8 sufficient gas-water contacts for methane hydrate formation. However, the SDS-DS showed  
9 more outstanding storage performance compared to DW and SDS solution (Table 2). SDS-DS  
10 exhibited about the same methane storage capacity as DW, but faster storage rates (the inner  
11 plots in Fig. 7) than DW. The time to achieve 90% of this perfect capacity ( $t_{90}$ ) under 5.0 MPa  
12 for SDS-DS was about 60 min, which was less than that of DW (200 min) with the same silica  
13 content, and also less than that reported for methane storage in DW (160 min) under 8.6 MPa  
14 (Wang et al., 2008). SDS-DS has similar storage rates as SDS solution, while it can capture  
15 more volumes of methane than SDS solution. Therefore, highly dispersed SDS-DS system  
16 combines storage advantages of dispersed DW and active SDS solution, and has dual  
17 enhancement effects on methane hydrate formation. Enhancements of storage capacity and  
18 formation rate should probably be attributed to better dispersion and surface active of  
19 SDS-DS sample. However, the aggregation of partial SDS-DS powders destroyed its original  
20 dispersive property after hydrate dissociation. As can be seen in Fig. 8, after one time  
21 hydration and dissociation, some SDS-DS droplets (7.5 wt% silica) aggregated and formed  
22 partial continuous bulk water.

1 In order to illustrate SDS-DS's enhancing hydration and micro-droplet aggregation, a  
2 hypothesis of methane hydrate formation and dissociation in SDS-DS system was raised in  
3 Fig. 9. In the SDS-DS system, micro-droplets with a size of 1~2  $\mu\text{m}$  were encapsulated by  
4 hydrophobic silica nanoparticles and kept isolated each other (Fig. 9A). Dispersed SDS-DS  
5 contributed abundant gas transport and gas-water interfacial surface area to hydrates  
6 nucleation and growth. For each solution droplet, it can be taken as a miniature hydration  
7 system based on SDS solution. During hydration process, thin methane hydrate layer formed  
8 around the surface of droplets (Fig. 9B) and grew thick gradually (Fig. 9C). Previous studies  
9 have reported that branches of porous fibre-like hydrate were formed in the presence of  
10 surfactants and increased gas-water contacts for further hydrate crystals growth (Yoslim et al.,  
11 2010). Thus SDS-DS system has dispersion of DW and surface active of SDS. Especially,  
12 SDS-DS sample (7.5 wt% silica) with better dispersion enhanced more gas-water contacts  
13 than other samples and stored the most methane. Solution droplets expanded during their  
14 conversion into hydrate, so adjacent hydrate particles would freeze each other until the end of  
15 hydration (Fig. 9D). When hydrate dissociation, freezing hydrate particles melted and  
16 aggregated to bigger droplets. Partial aggregated bigger droplets became continuous solution  
17 (Fig. 8) and could not recover their original isolated droplets again. Stabilized surfactant-DS  
18 with enhancement effect on hydration will be further investigated.

#### 19 **4. Conclusion**

20 In summary, we use the highly dispersed surfactant-DS as a storage medium to  
21 significantly improve methane uptake kinetics and storage capacity for the first time.  
22 Surfactant-DS combines the advantages of dispersed DW and active SDS solution. Not only

1 our SDS-DS can provide considerable gas-liquid contacts, but also each droplet is a micro  
2 hydration system with surfactant. SDS-DS system can store methane faster compared to DW  
3 and has higher storage capacity compared to SDS solution under a relative low pressure. The  
4 results will provide useful information on kinetics of gas to solid hydrate in static dispersed  
5 solution. However, after freezing hydration and warming dissociation, SDS-DS droplets  
6 aggregate to bigger droplets and even form partial continuous solution. The destroyed droplets  
7 cannot recover their original dispersive state, so further study will be focused on stabilized  
8 surfactant-DS.

7  $\Delta V$  volume increment, cm<sup>3</sup>

8 ***Subscripts***

9 0 initial state

10 1 small cavities of hydrate

11 2 large cavities of hydrate

12 90 gas consumption reaches 90 % of final storage capacity

13 e final (equilibrium) state

14  $t$  state of time  $t$

15 STP standard temperature and pressure

16 ***Superscripts***

17 g gas phase

18 h hydrate phase

19 l liquid phase

20 Si hydrophobic silica HB630

1

2 **Table 1.** Mixing ratios of 0.03 wt% SDS solution to silica HB630 for preparing SDS-DS.

SDS solution weight (g)	Silica weight (g)	Silica contents (wt %)
48.75	1.25	2.5
47.50	2.50	5.0
46.25	3.75	7.5
45.00	5.00	10.0

3 **Table 2.** Experimental conditions and methane storage properties of all the systems.

Samples <sup>1</sup>	Weight (g)	Pressure (MPa)	Temperature (K)	Capacity <sup>2</sup> (m <sup>3</sup> ·m <sup>-3</sup> )	Maximum rate (m <sup>3</sup> ·m <sup>-3</sup> ·min <sup>-1</sup> )
Bulk water	15.00	5.0	273.2	~7.00	~0
SDS solution	15.00	5.0	273.2	150.02	7.07
DW (7.5 wt% SiO <sub>2</sub> )	15.00	5.0	273.2	170.56	5.90
SDS-DS (2.5 wt% SiO <sub>2</sub> )	15.00	5.0	273.2	161.89	7.26
SDS-DS (5.0 wt% SiO <sub>2</sub> )	15.00	5.0	273.2	167.32	7.29
SDS-DS (7.5 wt% SiO <sub>2</sub> )	15.00	5.0	273.2	172.96	7.44
SDS-DS (10.0 wt% SiO <sub>2</sub> )	15.00	5.0	273.2	160.80	7.36

4 <sup>1</sup> Concentrations of SDS in its solution and its dry solution systems are 0.03 wt%.

5 <sup>2</sup> Each group of *t-T-P* points determines an instantaneous capacity value. Each capacity listed  
6 above is the average value of the last 15 instantaneous capacity values for each test  
7 (experimental time: 600 min; data-collection interval: 10 s). The error between each average  
8 value and each one of the last 15 capacity values is  $\pm 0.15 \text{ m}^3 \cdot \text{m}^{-3}$ , which is acceptable in our

1 tests.
