Abstract: Privacy is a very diverse field of research and due to its subjective nature open to many interpretations and representations. Information Privacy forms a key component of Privacy related research, particularly its importance to Information Technology and the increasing collection and use of personal data. Within any rapidly expanding body of knowledge the terminology used needs to be clearly defined, categorized and relationships established. This paper provides such a taxonomy for Information Privacy. It has evolved through the study and application of Information privacy and its effects on the operation, creation and ongoing administration of Virtual Collaborations. The knowledge provided from an information privacy taxonomy can be used to formulate better information privacy policies, practices, and privacy enhancing technologies (PET’s).

Key-Words: Information Privacy, Information Security, Taxonomy, Collaborative Environments, Meta Privacy.

1 Introduction
By definition, taxonomy is "... A scheme that partitions a body of knowledge and defines the relationships among the pieces. It is used for classifying and understanding the body of knowledge." [1]. As a field of research grows there comes a point in time that the subject matter should be at least theoretically classified into its bases, principles, procedures and rules. The area of Information Privacy, in particular, in the expanding field of Collaborative Environments, is in need of such an arrangement. This paper addresses this issue by providing an general introduction of overview of a taxonomy for Information Privacy in Collaborative Environments. The full taxonomy has not been included due to space limitations, but a much more detailed and expanded body of work has been produced by the authors of this paper.

The paper does provide a high level of detail and knowledge suitable for taxonomy of Information Privacy. Focus has been placed on Collaborative Environments (C.E.’s) due to their inherent data sharing nature and the related privacy issues they create. With the use of C.E.’s in many areas, including the health and intelligence sectors, there are numerous personal data privacy problems to address. Following on from the introduction, section 2 provides a background on the area of Information Privacy. The information privacy issues in Collaborative Environments are discussed in greater detail in Section 3. Section 4 provides the taxonomy proposal and its three key dimensions, followed by a conclusion in Section 5, and References at the end.

2 Background and Related Work
Before continuing it seems that no privacy proposal is complete without some mention of the 'type' of privacy, one is addressing. This is especially important when the subject of importance is a taxonomy. From a definition of a particular dimension of privacy one can loosely categorize the solutions aimed at each of them. Privacy in general is very subjective and means different things to different people. Common among all interpretations is the perspective that privacy is a human right but is context and environmentally dependent. A number of common privacy dimensions have been defined that have gained wide acceptance [2]. They are as follows:

- Privacy of the person
- Privacy of personal behavior
- Privacy of personal communications
- Privacy of personal data

Personal data, also referred to as information privacy is the focus of this taxonomy. In [2] Clarke also provides a well referenced definition of information privacy after initially stating it as being
combination of personal communication privacy and personal data privacy. His formal definition of information privacy is "... the interest an individual has in controlling, or at least significantly influencing, the handling of data about themselves." [2]. The Common Criteria (CC) [3] provides a more formal requirements based definition for providing "... user protection against discovery and misuse of identity by other users.". As you can see from the CC definition, it is information systems-requirements focused, with emphasis on identity protection. Identity protection is a major component of information privacy but by no means represents the complete embodiment of its full meaning.

The other forms of privacy are just as important including privacy of the person and privacy of personal behavior. Privacy of the person concerns the reliability and truthfulness of an individual's physical characteristics and body. For example it may include an employee being required to take a compulsory medical and blood test before joining and organization. Privacy of personal behavior also relates to the individual physical person but is concerned with their actions, beliefs, and lifestyle. This encompasses such things as sexual preferences, religious and political affiliations, and perhaps parenting methods. The privacy extends over both the public and private domains. Communications Privacy is concerned with un-monitored or non-intercepted communication between individuals. When combined with data privacy forms a working concept of Information Privacy, as data privacy is concerned with data about individuals that the data owners may wish to keep private.

The Platform for Privacy Preferences (P3P) of W3C [4] is a significant effort to enable web and potentially information system users to gain control over their private information. Open to much debate as to whether it is truly a PET; it does provide automated notice and privacy policy reading from user web browsers. P3P has generated a lot of interest and naturally a lot of research and work material in the area. The scope of which is beyond this paper. What is of interest is its use of metadata to represent privacy policy settings of entities to further enhance their privacy protection. P3P can be used as an assurance mechanism for an entity to confirm the privacy policy preferences in a settings matching process. Metadata tags-and document structures are used to store an entity’s privacy settings and preferences. The entity requesting personal information also uses the metadata tags and document structures to represent their privacy policies and operational procedures.

3 Information Privacy requirements for Collaborative Environments

Collaborative environments present major challenges to privacy. This fact is highlighted by Duan and Canny in [5] where they state: "By its nature, collaboration involves the exchange of information between collaborators. It may also involve automation ... ". There is a need to establish a balance between the benefits collaborative environments provide for knowledge discovery and sharing against the protection of individual and organizational privacy needs. In many countries now and in the immediate future privacy protection is enforceable by a number of laws and regulations. Privacy is no longer an issue for ad-hoc consideration or as an after thought once a system has been implemented. This is especially so in Collaborative Environments, due to their increased sensitivity and potential risks to privacy. Organizations and users need better control over how people gain access to each other and their personal information [6].

While privacy is a popular subject in relation to Collaborative Environments literature it has not been adequately examined in its own right. Rather, is has largely been addressed as an issue of security by system designers. From what we are aware there has been no substantial amount of research done into privacy protection in Collaborative Industrial Environments. This paper, and further more extensive work by the authors, provides an introduction and overview of a taxonomy for information privacy in collaborative environments (C.E.’s). The aim is to provide an organized approach to information privacy in C.E.’s. Providing clear classifications and categorizations of the many components and dimensions present for future knowledge and understanding in the area.

4 Overview of an Information Privacy Taxonomy

We have identified three dimensions that make up the highest level of the information privacy taxonomy. These dimensions are space, time, and matter. All are inter-related and have different influences over information privacy. The dimensions translate to three corresponding views of information privacy within a collaborative environment. The views are Structural View, Computation View, and Content View respectively. Each of the dimension and corresponding views are
discussed in more detail in the following sub-sections.

4.1 Dimension 1: Computation View
The time dimension, and therefore the computation view, reflects the level of privacy protection. Its time relevance relates to the amount of time and resources required to compromise the stated level of privacy protection. Three categories of privacy protection have been defined, each classified from the highest level of protection to the lowest. The three include Ideal Privacy, Computational Privacy, and Fragile Privacy, listed from highest to lowest protection respectively.

NATURE (N) = Level of Privacy Protection (pp).

4.1.1 Ideal Privacy
Privacy Protection: pp = \infty for Ideal Privacy

With Ideal Privacy, users at all times determine when, how and what personal information is revealed. Additionally personal data owners decide to what extent others can utilize their information once access is granted. Ideal Privacy gives users complete control over their personal data and more generally all of their information privacy concerns.

Definition 1: Ideal Privacy provides the highest level of privacy protection (theoretical and practical), providing users with complete control over all of their privacy concerns. No amount of computation can compromise ideal privacy protection.

Equation (1): \{ As t->\infty AND r->\infty; pp = \infty \}.

This translates to: Given an infinite amount of time (t) (t \to \infty) and unlimited computational resources (r) (r \to \infty) privacy protection (pp) will always remain at the highest level and stay uncompromised (pp = \infty).

4.1.2 Computational Privacy
Privacy Protection: pp \to 0 for Computational Privacy

With Computational Privacy, users are provided with significant control over when, how and what personal information is revealed. Additionally personal data owners are the primary entities deciding to what extent others can utilize their information once access is granted. Computational Privacy gives users a high level of control over their personal data and more generally all of their information privacy concerns. However, system owners and data collectors also have a level of control over personal data collection and use, once terms have been agreed upon with personal data owners. Computational Privacy means that it is infeasible to compromise privacy protection within reasonable operational parameters. However, given a very long amount of time and a very large amount of resources, it may be possible to compromise the level privacy protection.

Definition 2: Computational Privacy provides a medium or operational level of privacy protection, providing users with significant but not complete control over all of their privacy concerns. With an infinite or unreasonably large amount of computation, computational privacy protection can be compromised.

Equation (2): \{ As t->\infty AND r->\infty; pp \to 0 \}.

This translates to: Given an infinite amount of time (t) (t \to \infty) and unlimited computational resources (r) (r \to \infty) privacy protection (pp) will eventually be compromised (pp \to 0).

4.1.3 Fragile Privacy
Privacy Protection: pp \to 0 for Fragile Privacy

Given a reasonable amount of time and resources, fragile privacy can be compromised. This level of privacy protection is only deemed effective against weak threats and attacks. Unfortunately, a large number of collaborative environments (C.E.'s) are of this nature, when they should be offering higher levels of privacy protection. As the adaptation and uses for C.E.'s have increased so has the need for better privacy protection. Many internet sites are still of the format that an entity either accepts the organizations stated privacy as is, or the entity is denied access to their services and resources. Additionally, it is normally the case that if the entities consent is given, control over most personal data is relinquished to the information collectors. What further exacerbates the problem is that for the majority of entities, they do not really pay attention to the finer details of the privacy policy they are agreeing to. This results in a privacy agreement that is very fragile in its nature and understanding. Either the entity had no choice but to agree to the conditions, or they did not understand what they were agreeing to.

Definition 3: Fragile Privacy provides the lowest level of privacy protection, providing users with...
limited control over all of their privacy concerns. With a reasonable amount of computation, fragile privacy protection can be compromised.

Equation (3): \( \{ \text{As } t \rightarrow N_i \text{ AND } r \rightarrow N_i, pp = 0 \} \).

This translates to: Given a reasonable amount (\( N_i \), a large value) of time (\( t \rightarrow N_i \)) and a reasonable amount (\( N_i, \text{ a large value} \)) of computational resources (\( r \rightarrow N_i \)) privacy protection (pp) will be compromised (pp = 0).

4.2 Dimension 2: Content View
The matter dimension, and therefore the content view, reflects the privacy of collaborative environment objects. Its matter relevance relates to the different types of data that require privacy. Three categories of objects have been defined and each classified accordingly. The three include Data Privacy, Identity Privacy, and Meta Privacy.

NATURE (N) = Objects Privacy (Obj)

4.2.1 Data Privacy
Object: Data -> knowledge and information -> (Data, Text, Emails, Documents, Files, Logs, Transcripts, etc)

Data privacy is the protection of an entities personal data that is being collected, shared, and stored. Ideally the protection is complimented with the entity having complete control over their personal data. There are a number of formal definitions for data privacy that are useful in our taxonomy representation. One such definition refers to data privacy as the "... evolving relationship between technology and the legal right to, or public expectation of privacy in the collection and sharing of data." [7]. The problem in virtual collaborations is that they are environments made up of interconnected heterogeneous information systems that have different privacy rules and laws governing their operation.

Therefore, those tasked with the management and administration of virtual collaborations must take the responsibility for securing personal data and monitoring its secure use. Further, the control and management of an entity's personal data, collected in a collaborative environment, should be tasked to that data owner. This approach has the added benefit of distributing the privacy protection responsibilities between system users and owners. Not only are data owners responsible for their own data but they have the desired control over what data is accessible, by who and for what specific purposes it can be used.

Using this method also conforms to most privacy policies and legislations either in use or being introduced in many organizations.

4.2.2 Identity Privacy
Object: Entities -> individuals, groups, and organizations -> (Identity, Identification, Authentication)

One of the top five privacy issues for the year 2005 was Identity Management, specifically the need to balance privacy and security in such a context [8]. The same report states 'Identity is key to protecting personal information and privacy rights'. In an information system and in a broader virtual collaboration an identity is a set of data about an entity (individual, group, or organization) that could be used to differentiate them from other entities in the same environment.

Therefore, identity protection involves securing an entity's identity from unwanted disclosure or discovery. From a privacy preserving perspective, identity protection is concerned with entity control over how they interact with the information system and other entities within the system. Entities should have a choice as to when, how and to who they reveal their identity to and also who has access to it. Further, transactions and interactions should be able to be carried out in any of the following ways:

- Identifiability: the ability to differentiate an entity or transaction from a group of other entities or transactions.
- Pseudo-Anonymity: the inability to differentiate an entity or transaction from a group of other entities or transactions in the normal course of events.
- Anonymous: the total inability to differentiate an entity or transaction from a group of other entities or transactions.

It is also possible for a single entity to have multiple pseudo-anonymous identities, also referred to as 'nym's' [9]. A 'nym' is a created identity used by an entity that does not wish to reveal their true identity. They are normally associated with virtual or electronic environments and are a virtual invented or fabricated representation of an entity. Nym's are a very useful technology for privacy protection as they may be anonymous or pseudo-anonymous in nature. Entities may utilize different nym's for different settings or use the same one for all Internet and virtual transactions. Likewise, in an ideal setting it should also be possible for many entities to use the same 'nym'. In this papers context this would allow all members of a group or organization to use the
single 'nym'. Individuals using the same 'nym' would not allow true identity protection. That is, unless the entities had consented to absolute disclosure and control over each others personal data. When using multiple identities it should not be possible for other entities to deduce that any two identities represent the same entity. That is, there should be no way that a relationship can be established or shown between any two system pseudo-anonymous or anonymous identities. This includes past, present and future system and processing data, actions, and behaviors.

The use of pseudo-anonymous and anonymous identities is often in conflict with a long held misconception that a person's true identity needs to be known for authenticated access to information systems and their resources. It is now widely accepted that in most cases a suitable pseudo-anonymous identity is just effective for the majority of authorization techniques. That is, it is possible to authorize access by a form of identity rather than authenticating access through an entities true identity. Therefore, the three key aspects to identity privacy are [10]:

- Identity
- Identification
- Authentication

There is a complex relationship between all of the aspects, especially from an information systems privacy and security perspective. Further discussion of this subject is beyond the scope of this paper due to space limitations.

4.2.3 Meta Privacy
Object: Metadata and Metastructure Information -> Approaches and Purpose: -> (1) Metadata and Metastructure Content: {Personal Privacy Protection versus Privacy Policy and Preferences Representation}; (2) Unlinkable and Unobservable -> {Risks versus Benefits}.

Meta Privacy is a relatively new term, first formally defined in [11]. A common definition for the word Meta is as a prefix used in an information systems context as meaning "relating to" or "based on". More formally it is a prefix meaning "information about". So when used in conjunction with the term privacy, to formulate the term Meta Privacy, it means information about privacy. Meta privacy is concerned with the information used to support other system services and processors that impact upon an entities privacy. An entity may be an individual, group, or organization. Meta Privacy encompasses the use and management of metadata and metastructure information. It is the metadata and its implementation details, metastructure, which can be the source of either privacy enhancing benefits or privacy invasive drawbacks. This is determined by metadata use, such as P3P [Above], or abuse.

Meta Privacy is defined by the following definition: 'Meta Privacy means ensuring the security and privacy of data about privacy and personal data. Meta privacy is concerned with the security and privacy of the information used to support other system services and processors that may impact upon an entities privacy. This encompasses the protection of metadata and metastructure information that may reveal an entities identity and other personal information' [11].

The Metastructure components are composed of the data concerned with the functioning and structural details of the information systems and their many components. This may include information on the access controls used in the systems, the system and policy frameworks which supplies rules regarding the relationships within and between the systems and their policies, and other information about the system and component structures and the interoperation. When dealing with information systems and more generally collaborative environments the management of metadata and metastructure information involves serious privacy considerations.

The controlled use, access to, and storage of metadata and metastructure information must be guided by stringent privacy protection procedures. It is the metadata and its implementation that can be the source of either privacy enhancing benefits or privacy invasive drawbacks. This applies also to the use of metastructure information. Both types need to be protected and is the focus of this sub-section.

4.3 Dimension 3: Structural View
The space dimension, and therefore the structural view, reflects the privacy of collaborative environment entities. Its space relevance relates to the different types privacy applied to various entities and relationships within the Collaborative Environment. Three categories of entities have been defined and each classified accordingly. The three include Individual Privacy, Group Privacy, and Organizational Privacy.

NATURE (N) = Privacy of Entities and Relationships (Rln)

4.3.1 Individual Privacy
**Individual Privacy** is the privacy of an individual entity. In this paper the context of use refers an entity or user within the Collaborative Environment.

It is an entity that has provided personal data that they wish to remain private or protected for privacy reasons. At the most fundamental level each individual entity that is a member of the collaborative environment (C.E.) should be entitled to privacy protection. This encompasses any personally identifiable information (PII) they have provided during registration and ongoing membership of the C.E.. If an entities personal data is revealed without their permission, this would constitute a privacy breach. Individual privacy includes protecting both personal data and related metadata and metastructure information. The protection supports the concept of unobservability.

An individuals perception of privacy is highly subjective and context specific. Therefore, what constitutes privacy protection in the C.E. should be clearly stated in the associated privacy policy and operational procedures. Anonymously and pseudonymous identities should be available for use by individual entities when ever possible. The use of multiple identities of this type should also be available to support unlinkability.

**Definition 4**: **Individual Privacy** is concerned with the protection and preservation of an individual entities privacy.

Individual privacy protects each user from undesirable intrusions and the maintenance of their personal space. In an information privacy context it means that a users personal information is protected from unauthorized access and use. As individuals may be members of a number of groups, and organizations they are able to establish both Committed and Not-Committed privacy relationships.

**Equation (4)**: \( l \rightarrow 1 (l_1 \parallel e); l \rightarrow n (l_1 \parallel e); m \rightarrow n (l_1 \parallel e) \)

(Note: \( l_1 \) means Not-Committed and \( e \) means Committed)

This states that within a Collaborative Environment (C.E.) Individual Privacy is maintained for any entity member. The entities provided privacy protection may be a single entity; one entity to \( n \) entities, or even \( m \) to \( n \) entities with the C.E.. The entities may be either committed or not-committed to the their own privacy protection provided by the C.E..

**4.3.2 Group Privacy**

Groups in this context are those with no entity commitments. They are often dynamic and ad-hoc groupings in nature as a result. The members of the groups and the groups themselves need their own levels of privacy protection depending on the needs of the membership and group. These needs are also influenced by the reason for group existence and the data the group handles and produces. When members join and leave the group there needs to be at least Fragile Privacy protection maintained over the group and entity members data.

Within a virtual collaboration there may be any number of formal and informal groups. Each of these has their own set of privacy concerns that must be addressed. A group, like an individual, produces personal information that should be under the management of the group. The group controls who, when, where and what information is revealed to other entities. Depending on the nature of the group, formal or informal, there are different levels of privacy sensitivity to the group for different members. Membership is also dependant on other factors including time, roles, requirements and personal needs.

**Definition 5**: **Group Privacy** is concerned with the protection and preservation of a Group's and each Non-Committed individual group member's privacy.

Group privacy protects the personal information of the group and each member in the group. The privacy protection is provided regardless of the non-committed nature of the group members. Groups may be ad-hoc, dynamic and time dependent relations. Group Privacy aims to support the varying non-committal nature of group memberships. This means that Group Privacy ensures that during the formation, duration, and after they have been dispersed the privacy of the group and each entity member of the group is protected.

**Equation (5)**: \( l \rightarrow 1 (l_1); l \rightarrow n (l_1); m \rightarrow n (l_1) \)

(Note: \( l_1 \) means Not-Committed).

This states that within a Collaborative Environment (C.E.) Group Privacy is maintained for any group and group member. The entities provided privacy protection may be a group with single membership, a group with one entity to \( n \) entities, or a group with \( m \) to \( n \) entities. The entities are not-committed to the groups privacy provided. This is as a result of the Group being defined by ad-hoc, informal and non-committed entity membership.

**4.3.3 Organizational Privacy**
Organizations in this context are those with formal and informal commitments required by their entity membership. They are often structured, planned, and governed by a set of policies and procedures. The members of an organization are committed to privacy. The privacy is maintained with when members join and leave the organization. Within a Collaborative Environment (C.E.) there may be any number of formal and informal organizations. Each of these has its own set of privacy concerns that must be addressed. An organization, like an individual and group, also produces 'personal' information that should be under the management of the organization and afforded privacy protection. The organization controls who, when, where and what information is revealed to other entities. Depending on the nature of the organization, formal or informal, there are different levels of privacy sensitivity to the organization for the different entity members. Membership is also dependant on other factors including time, roles, requirements and personal needs. Organizations also have a number of additional privacy issues that need to be managed. This includes the changing members of the group and ensuring privacy policies are still adhered to. What's more, this is even after organizational membership has been relinquished.

Definition 6: Organizational Privacy is concerned with the protection and preservation of an Organization's and each Committed individual organizational member's privacy.

Organizational privacy protects the sensitive personal information and activities of an organization, in addition to the personal information of the organizational members. Individual entities are committed to organizational privacy protection as well as their own and each entity within the organization. Organizations generally have more stable and committed memberships that do groups. This allows formal individual commitments, privacy policy development, and privacy focused operating guidelines.

Equation (6): \(1 \rightarrow 1 (e); 1 \rightarrow n (e); m \rightarrow n (e): \text{where } m = n \text{ OR } m \neq n\)
(Note: e means Committed)
This states that within the Collaborative Environment (C.E.) Organizational Privacy is maintained for any organization and organizational member. The entities provided privacy protection may be an organization with single membership, an organization with one entity to n entities, or an organization with m to n entities. The entities are committed to the organizational privacy provided. This is as a result of the organization being defined by committed entity membership often governed by set privacy policies, guidelines and operating procedures.

5 Conclusion
Privacy, and more specifically, Information Privacy, has been gaining research momentum of late. The increased interest in the field has generated numerous new definitions, terminologies, and proposed solutions to the complex privacy issues. With the increasing abundance of material in the field it has become difficult to define and classify information privacy components. This paper has addressed this issue by providing an Information Privacy taxonomy. The contribution proposed has been limited by the space restrictions of the paper, but has provided a unique arrangement of many of the important information privacy components and dimensions.

Focusing the taxonomy on a Collaborative Environment Information Privacy issues has highlighted three key dimensions of the taxonomy. The dimensions are the Computation View, the Content View, and the Structural View. Within each there are additional categorizations to clearly define each of the dimensions and elements contained within them. The Computation View had three sub-classifications of Ideal Privacy, Computational Privacy, and Fragile Privacy as they relate to the level of Privacy Protection. The content view also had three sub-categories of Data Privacy, Identity Privacy, and Meta Privacy as they relate to objects. Finally, the Structural View likewise has three sub-categories of Individual Privacy, Group Privacy, and Organizational Privacy as they relate to entities and their privacy relationships.
