Abstract—In this paper, the uplink and downlink sum-mean-squared error (MSE) duality for multi-hop amplify-and-forward (AF) multiple-input multiple-output (MIMO) relay channels is established, which is a generalization of several sum-MSE duality results. Unlike the previous results that prove the duality by calculating the MSEs for each stream directly, we introduce an interesting perspective to the relation of the uplink-downlink duality based on the Karush-Kuhn-Tucker (KKT) conditions associated with both uplink and downlink transceiver design optimization problems.

Index Terms—Amplify-and-forward, uplink-downlink duality, MIMO relay.

I. INTRODUCTION

One of the key techniques to solve the downlink optimization problems is to transform the downlink problem into an uplink problem via uplink-downlink duality relationship, and solve it in the uplink domain since the uplink channel has a simpler mathematical structure, and less coupling of variables.

The MSE duality for a single-hop was established under a sum-power constraint when perfect channel state information (CSI) is available at all the nodes in the system in [1]-[2], and for imperfect CSI in [3]-[5]. It has been shown that any MSE point achievable in the uplink can also be achieved in the downlink under the sum-power constraint. Recently, the uplink-downlink sum-MSE duality for single-hop systems [1]-[5] has been extended to two-hop and multi-hop AF MIMO relay systems in [6] and [7], respectively.

Due to the multi-hop topology, MSE is a complicated function of the source, relay and receiver matrices, which makes both the proof of duality and the optimization problems associated with multi-hop MIMO relay networks much more challenging than the existing works with simpler network topology. As a direct application of the duality results in [7], [8], the complicated downlink MIMO multi-hop transceiver (source precoding, relay amplifying and receiver matrices) design problems can be carried out efficiently by focusing on an equivalent uplink MIMO multi-hop relay system.

A. Contributions of This Work

1) MSE duality in [1]-[4] and [7] is established by calculating the MSE of each stream of all users directly. Here, we establish the uplink-downlink duality based on the KKT conditions of the uplink and downlink transceiver optimization problems, which is an interesting perspective to the relation of the uplink-downlink duality.

2) The duality result established in this paper generalizes the results in [5] and [6], which also use KKT conditions to prove the sum-MSE duality for single-hop and two-hop MIMO channels, respectively.

3) The sum-MSE duality for multi-hop AF MIMO relay systems in [7] is established under the assumption that receivers employ linear minimum MSE (MMSE) receivers, the sum-MSE duality result in this paper is applicable to any kind of linear receiver.

The notations used in this paper are as follows. (·)T and (·)H denote transpose and conjugate transpose, respectively. E[·], I_N and tr(·) denote the statistical expectation, N × N identity matrix and trace, respectively. For matrices A_i, \( \bigotimes_{k=1}^{l} (A_i) \triangleq A_1 \ldots A_k \). For example, \( \bigotimes_{j=1}^{3} (A_i) \triangleq A_1 A_2 A_3 \) and \( \bigotimes_{j=3}^{l} (A_i) \triangleq A_3 A_2 A_1 \). \( \prod_{j=l}^{k} (A_i) \triangleq A_l \ldots A_k \) for \( l \leq k \) and is equal to identity matrix for \( l > k \).

II. SYSTEM MODEL

Similar to the system model in [7]-[8], we consider a wireless communication system with K users, \( L - 1 (L \geq 2) \) half-duplex AF relay nodes, and one base station (BS) node, where each node is equipped with multiple antennas. The number of antennas at the lth relay node of the uplink system is \( N_l, l = 1, \ldots, L - 1 \) and the BS is equipped with \( N_L \) antennas. Due to the path-loss in the wireless channels, we assume that the signal transmitted by the lth node can only be received by the \( (l + 1) \)th node, so the signal transmitted from the source node travel through \( L \) hops to reach to its destination. The rth user is equipped with \( M_r \) antennas, and transmits (receives) \( M_r \) independent data streams.

![Fig. 1. Uplink multi-hop AF MIMO relay system.](image-url)
A. Uplink MIMO Relay System

The uplink MIMO multi-hop relay system is shown in Fig. 1. The data streams $s_i^{UL} \in C^{M_i \times 1}$ is linearly precoded by the $i$th user with the source precoding matrix $B_i \in C^{M_i \times M_i}$ and the $i$th user transmits the precoded signal vector $u_i = B_i s_i^{UL}$ to the first relay node. We assume complex, zero mean, independent and identically distributed (i.i.d.) data streams $B$ and the additive white Gaussian noise (AWGN) vector at the first relay.

The $l$th relay node, $l = 1, \ldots, L - 1$, applies $F_{l+1} \in C^{N_l \times N_{l-1}}$ to amplify and forward the received signals, which is given by

$$y_i^{UL} = H_i s_i^{UL} + v_i$$

where $H_i \in C^{N_l \times N_{l-1}}$, $i = 1, \ldots, K$, is the channel matrix from the first relay node and the $i$th user and $v_i$ is the $N_l \times 1$ i.i.d. additive white Gaussian noise (AWGN) vector at the first relay.

The received signal at the first relay node is given by

$$y_1^{UL} = \sum_{i=1}^{K} G_i B_i s_i^{UL} + v_1$$

where $G_i \in C^{N_1 \times M_i}$, $i = 1, \ldots, K$, is the equivalent channel matrix between the first relay node and the $i$th user and $v_1$ is the $N_1 \times 1$ i.i.d. additive white Gaussian noise (AWGN) vector at the first relay.

The received signal vector of size $N_{l-1} \times 1$ is amplified and forwarded when the $l$th relay node receives, $l = 1, \ldots, L - 1$. From (1) and (4), the received signal vector at the $l$th relay node is given by

$$y_i^{UL} = A_l \sum_{j=1}^{K} G_j B_j s_j^{UL} + \hat{v}_i$$

where $A_l$ is the equivalent channel matrix between the first relay node and the $l$th relay node, and $\hat{v}_i$ is the equivalent noise vector given by

$$A_l = \begin{cases} \bigotimes_{i=1}^{l} (H_i F_i), & l = 2, \ldots, L \\ I_{N_1}, & l = 1 \end{cases}$$

$$\hat{v}_i = \sum_{j=2}^{l} \left( \bigotimes_{i=1}^{j-1} (H_i F_i) v_{j-1} \right) + v_1, \quad l = 2, \ldots, L$$

Here $H_i \in C^{N_i \times N_{i-1}}$, $i = 2, \ldots, L$, is the channel matrix at the $i$th hop, and $v_1$ is the i.i.d. AWGN of the $l$th node of the uplink system, $l = 1, \ldots, L$. We assume that all noises are complex signals with zero mean and unit variance.

From (5), the covariance matrix of $\hat{v}_i$ can be written as,

$$C_i = \mathbb{E} \left[ \hat{v}_i (\hat{v}_i)^H \right] = \begin{cases} \sum_{j=2}^{l} \left( \bigotimes_{i=1}^{j-1} (H_i H_i^H) \bigotimes_{i=j}^{l} (F_i^H F_i^H) \right) + I_{N_1}, & l = 2, \ldots, L \\ I_{N_1}, & l = 1 \end{cases}$$

To estimate the data streams transmitted, the BS applies a linear receiver, i.e., $\hat{s}_j^{UL} = W_j y_j^{UL}$, which is given by

$$\hat{s}_j^{UL} = W_j \left[ A_l \sum_{i=1}^{K} G_i B_i s_i^{UL} + \hat{v}_l \right], \quad j = 1, \ldots, K$$

where $W_j$ is the weight matrix of the linear receiver of size $M_j \times N_L$. From (3) and (7), the MSE matrix of the $j$th user, can be written as

$$\mathbf{E}_{j}^{UL} = \mathbb{E} \left[ (\hat{s}_j^{UL} - s_j^{UL}) (\hat{s}_j^{UL} - s_j^{UL})^H \right], \quad j = 1, \ldots, K$$

$$\mathbf{E}_{j}^{UL} = \mathbb{E} \left[ (\hat{s}_j^{UL} - s_j^{UL}) (\hat{s}_j^{UL} - s_j^{UL})^H \right], \quad j = 1, \ldots, K$$

where $A^{UL} = \sum_{i=1}^{K} G_i B_i H_i^H$, $B^{UL} = \sum_{i=1}^{K} G_i B_i H_i^H$, $C^{UL} = \sum_{i=1}^{K} G_i B_i H_i^H$, and $C^{UL}$ is the weight matrix of the linear receiver of size $M_j \times N_L$. From (1) and (2), the received signal vector $y_i^{UL}$ is given by

$$y_i^{UL} = A_l \sum_{j=1}^{K} G_j B_j s_j^{UL} + v_1$$

where $A_l$ is the equivalent channel matrix between the first relay node and the $l$th relay node, and $v_1$ is the equivalent noise vector given by

$$A_l = \begin{cases} \bigotimes_{i=1}^{l} (H_i F_i), & l = 2, \ldots, L \\ I_{N_1}, & l = 1 \end{cases}$$

$$\hat{v}_i = \sum_{j=2}^{l} \left( \bigotimes_{i=1}^{j-1} (H_i F_i) v_{j-1} \right) + v_1, \quad l = 2, \ldots, L$$

Here $H_i \in C^{N_i \times N_{i-1}}$, $i = 2, \ldots, L$, is the channel matrix at the $i$th hop, and $v_1$ is the i.i.d. AWGN of the $l$th node of the uplink system, $l = 1, \ldots, L$. We assume that all noises are complex signals with zero mean and unit variance.

From (5), the covariance matrix of $\hat{v}_i$ can be written as,

$$C_i = \mathbb{E} \left[ \hat{v}_i (\hat{v}_i)^H \right] = \begin{cases} \sum_{j=2}^{l} \left( \bigotimes_{i=1}^{j-1} (H_i H_i^H) \bigotimes_{i=j}^{l} (F_i^H F_i^H) \right) + I_{N_1}, & l = 2, \ldots, L \\ I_{N_1}, & l = 1 \end{cases}$$

To estimate the data streams transmitted, the BS applies a linear receiver, i.e., $\hat{s}_j^{UL} = W_j y_j^{UL}$, which is given by

$$\hat{s}_j^{UL} = W_j \left[ A_l \sum_{i=1}^{K} G_i B_i s_i^{UL} + \hat{v}_l \right], \quad j = 1, \ldots, K$$

where $W_j$ is the weight matrix of the linear receiver of size $M_j \times N_L$. From (3) and (7), the MSE matrix of the $j$th user,
Here $K_l$ is the equivalent channel matrix between the first relay node and the $l$th relay node in the downlink channel and $\bar{n}_l$ is the equivalent noise vector given by

$$K_l = \begin{cases} \bigotimes_{m=L-l+1}^{L-1} (H^HZ_{L-m+1}), & l = 2, \ldots, L-1 \\ \mathbf{I}_{N_{l-1}}, & l = 1, \end{cases}$$

$$\bar{n}_l = \begin{cases} \sum_{k=1}^{l-1} \bigotimes_{m=L-l+1}^{L-k} (H^HZ_{L-m+1}) \mathbf{n}_k + \mathbf{n}_l, & l = 2, \ldots, L-1 \\ \mathbf{n}_1, & l = 1, \end{cases}$$

where $\mathbf{n}_l$ is the i.i.d. AWGN vector at the $l$th relay node, $l = 1, \ldots, L-1$. The received signal vector at the $i$th user $i = 1, \ldots, K$ can be expressed as

$$y_{L}^{(i)} = G_i^HZ_LY_{L-1}^{{DL}} + \bar{n}_{L}^{(i)}$$

$$= G_i^HZ_LK_{L-1}H_L^H \sum_{i=1}^{K} P_i T_i s_{L}^{{DL}} + \bar{n}_{L}^{(i)}$$

where $\bar{n}_{L}^{(i)} = G_i^HZ_L\bar{n}_{L-1} + \bar{n}_l$ is the equivalent noise vector at the $i$th user.

From (16), the covariance matrix of $\bar{n}_l$, $C_l^{DL}$, at the $l$th relay node, $l = 2, \ldots, L-1$ and the covariance matrix of $\bar{n}_{L}^{(i)}$, $C_l^{(i)}$, at the $i$th user can be written as

$$C_l^{DL} = \sum_{k=1}^{l-1} \left( \bigotimes_{m=L-l+1}^{L-k} (H^HZ_{L-m+1}) \right) \bigotimes_{m=L-k}^{L-1} (Z_{L-m+1}H_m) + \mathbf{I}_{N_{l-1}}, \quad l = 2, \ldots, L-1, \quad \text{s.t.} \quad \sum_{k=1}^{L-1} S_{l}^{DL} = \mathbf{D}_l Y_{L}^{(j)}, \quad j = 1, \ldots, K,$$

$$C_l^{(i)} = G_i^HZ_LC_{DL}Z_L^H G_i + \mathbf{I}_{M_i}.$$ (19)

To estimate the data streams $s_{L}^{{DL}}$, $j$th user applies a linear receiver matrix $D_j \in C^{M_j \times M_j}$, i.e., $s_{L}^{{DL}} = D_j Y_{L}^{(j)}$, $j = 1, \ldots, K$, which is written as

$$s_{L}^{{DL}} = D_j G_j^HZ_LK_{L-1}H_L^H \sum_{i=1}^{K} P_i T_i s_{L}^{{DL}} + D_j \bar{n}_{L}^{(j)}.$$ (20)

The MSE matrix of the $j$th user, $j = 1, \ldots, K$, i.e., $E_j^{{DL}} = \mathbb{E} \left( (s_{L}^{{DL}} - s_{L}^{DL}) (s_{L}^{{DL}} - s_{L}^{DL})^H \right)$ can be written as

$$E_j^{{DL}} = \mathbf{I}_{M_j} - D_j G_j^HZ_LK_{L-1}H_L^T J - T_j^H H_L K_{L-1}H_L^H G_j D_j^H + D_j \left[ G_j^HZ_LK_{L-1}A^{DL} K_{L-1}H_L^H G_j + C_l^{(j)} \right] D_j^H$$

where $A^{DL} = H_L^H \sum_{i=1}^{K} T_i T_i^H H_L^T$.

The power consumption in the $l$th relay node

$$\text{tr} \left( \mathbb{E} \left[ X_{L}^{DL} (X_{L}^{DL})^H \right] \right) = \text{tr} \left( Z_{L}^{(i)} (K_l A^{DL} K_{L-1}^{(i)} + C_{DL}^{(i)}) Z_{L}^{(i)^H} \right).$$

The downlink transceiver optimization problem is formulated:

$$\min_{Z_l, T_l, D_l} \sum_{j=1}^{K} \text{tr} \left( E_{j}^{DL} \right)$$

s.t.

$$\sum_{j=1}^{K} \text{tr} \left( T_j T_j^H \right) \leq P_{1}^{DL},$$

$$\text{tr} \left( Z_l (K_l A^{DL} K_{L-1}^{(i)} + C_{DL}^{(i)}) Z_l^H \right) \leq P_{1}^{DL}, \quad \forall l \in \{2, \ldots, L\}$$

where (23) and (24) are the total transmit power at the users and transmission power constraints at each relay node, respectively, and $P_{1}^{DL}, l = 1, \ldots, L$, are the power limit.

### III. UPLINK-DOWNLINK DUALITY

The optimization problems (10)-(12) and (22)-(24) are both non-convex, but the objective functions and constraints of them are continuously differentiable. Thus the uplink-downlink duality can be established based on their KKT conditions [5].

#### A. The KKT Conditions of the Uplink Problem

The Lagrangian function of (10)-(12) can be written as

$$L^{UL} = \sum_{j=1}^{K} \text{tr} \left( E_{j}^{UL} \right) + \lambda_1 \left( \sum_{j=1}^{K} \text{tr} \left( B_j A_j^{UL} A_j^{UL^H} - P_{1}^{UL} \right) \right)$$

$$+ \sum_{j=2}^{L-1} \lambda_l \left( \text{tr} \left( F_l A_{j-1} A_{j-1}^{UL} A_{j-1}^{UL^H} + C_{l-1} \right) F_l^H - P_l^{UL} \right)$$

where $\lambda_1$ and $\lambda_l$, $l = 2, \ldots, L$, are the Lagrange multipliers of the power constraints in (11) and (12). The gradient function of (25) with respect to $B_k, F_l, W_k$ is given by

$$G_k^H A_k^{UL^H} W_k^H = \left( \lambda_1 I_{M_k} + \sum_{l=2}^{L} \lambda_l G_k^H A_{l-1} A_{l-1}^H A_l^H + C_{l-1} \right) F_l^H F_l A_{l-1} G_k$$

$$+ \sum_{j=1}^{K} G_k^H A_{j}^H W_j^H W_j A_j G_k$$

$$\left( \sum_{j=1}^{K} \text{tr} \left( E_{j}^{UL} \right) \right) + \sum_{j=1}^{K} \text{tr} \left( B_j A_j^{UL} A_j^{UL^H} - P_{1}^{UL} \right)$$

$$+ \sum_{j=2}^{L-1} \lambda_l \left( \text{tr} \left( F_l A_{j-1} A_{j-1}^{UL} A_{j-1}^{UL^H} + C_{l-1} \right) F_l^H - P_l^{UL} \right)$$

where we have used the identities from [9] that $\frac{\partial}{\partial Z^H} = A$, $\frac{\partial}{\partial Z} = B^T$, $\frac{\partial}{\partial Z} = A$, $\frac{\partial}{\partial Z} = -B^T$ and

$$B_k^H G_k^H A_k^{UL^H} = W_k \left( A_k A_{UL} A_k^{UL^H} + C_k \right),$$

(28)
\[
\frac{df_i(z)}{dz} = \frac{1}{2} \left[ \frac{\partial f_i(z)}{\partial z_l} + \frac{\partial f_i(z)}{\partial z_j} \right]. \quad \text{Here } i = \sqrt{-1}. \text{ The other KKT conditions associated with (10)-(12) are given below}
\]

\[
\lambda_1 \left( \sum_{j=1}^{K} \text{tr} \left( B_j B_j^H \right) - P_1^{UL} \right) = 0 \tag{29}
\]

\[
\lambda_l \left( \text{tr} \left( F_l \left( A_{l-1} A_{UL} A_{l-1}^H + C_{l-1} \right) F_l^H \right) - P_l^{UL} \right) = 0 \tag{30}
\]

\[
\lambda_1 \geq 0, \quad \sum_{j=1}^{K} \text{tr} \left( B_j B_j^H \right) \leq P_1^{UL} \tag{31}
\]

\[
\lambda_l \geq 0, \quad \text{tr} \left( F_l \left( A_{l-1} A_{UL} A_{l-1}^H + C_{l-1} \right) F_l^H \right) \leq P_l^{UL} \tag{32}
\]

**Lemma 1.** [Relation between the Lagrange multipliers, and the relay amplifying and receive matrices.]

For any solutions satisfying the KKT conditions (26)-(32), the Lagrange multipliers are

\[
\lambda_L = \sum_{k=1}^{K} \text{tr} \left( W_k^H W_k \right) \tag{33}
\]

\[
\lambda_{L-1} = \frac{1}{P_{DL}^{UL}} \text{tr} \left( F_L^H \left( H_L^{H} \sum_{k=1}^{K} W_k^H W_k H_L + \lambda_L I_{N_{L-1}} \right) F_L \right) \tag{34}
\]

\[
\lambda_l = \frac{1}{P_{DL}^{UL}} \text{tr} \left( F_{l+1}^H \left( \sum_{m=1}^{L-1} H^H_{m} F_{m+1} + \sum_{k=1}^{L} \lambda_k \otimes H_{m}^H \sum_{j=1}^{K} W_j^H W_j H_{l} \right) \right) \times \sum_{m=1}^{L-1} F_m^H + \sum_{k=1}^{L} \lambda_k \otimes H_{m}^H \sum_{j=1}^{K} W_j^H W_j H_{l} \right) \times \left( \sum_{m=1}^{L-1} F_m^H + \lambda_{l+1} I_{N_l} \right) F_{l+1}, \quad l = 1, \ldots, L-2. \tag{35}
\]

**Proof:** See Appendix A in [10]. \[ \Box \]

**B. The KKT Conditions of the Downlink Problem**

The Lagrangian function of (22)-(24) can be written as

\[
\mathcal{L}^{DL} = \sum_{j=1}^{K} \text{tr} \left( E_j^{DL} \right) + \alpha_l \left( \sum_{j=1}^{K} \text{tr} \left( T_j T_j^H \right) - P_l^{DL} \right) + \sum_{l=2}^{L} \alpha_l \left( \text{tr} \left( Z_l \left( K_{l-1} A_{DL} K_{l-1}^H + C_{l-1}^{DL} \right) Z_l^H \right) - P_l^{DL} \right)
\]

where \( \alpha_l \) and \( \alpha_l, \quad l = 2, \ldots, L, \) are the Lagrange multipliers of the power constraints in (23) and (24). The gradient function of (36) with respect to \( T_k, Z_i, D_k \) is given by

\[
H_k^H K_{k-1}^H G_j D_j H_k^H \]

\[
\begin{align*}
&= \left( \alpha_1 I_{M_k} + \sum_{l=2}^{L} \alpha_l H_k^H K_{l-1}^H Z_l^H Z_l K_{l-1}^H H_k^H \right) T_k \text{(37)} \\
&+ \sum_{j=1}^{K} H_k^H K_{k-1}^H Z_l^H G_j D_j^H D_j G_j^H Z_l K_{k-1}^H H_k^H \right) T_k \text{(37)} \\
&+ \sum_{j=1}^{K} H_k^H K_{k-1}^H Z_l^H G_j D_j^H D_j G_j^H Z_l K_{k-1}^H H_k^H \right) T_k \text{(37)}
\end{align*}
\]

where \( \alpha_1 \) and \( \alpha_l, \quad l = 2, \ldots, L, \) are the Lagrange multipliers of the power constraints in (23) and (24). The gradient function of (36) with respect to \( T_k, Z_i, D_k \) is given by

\[
\sum_{j=1}^{K} X_k^{(L)} G_j D_j^H T_j^H H_k Y_k^{(1)}
\]

\[
= \sum_{j=1}^{K} X_k^{(L)} G_j D_j^H D_j G_j^H Z_l K_{L-1} A_{DL} Y_k^{(1)}
\]

\[
+ \sum_{j=1}^{K} X_k^{(L)} G_j D_j^H D_j G_j^H Z_l K_{L-1} A_{DL} Y_k^{(1)}
\]

\[
= \sum_{l=k+1}^{L-1} \left( \sum_{m=1}^{L-1} H^H_{m} Z_{l-1} + C_{l-1}^{DL} \right) Z_l^H \tag{38}
\]

The other KKT conditions associated with the problem (22)-(24) for \( l = 2, \ldots, L \) are given below

\[
\alpha_1 \left( \sum_{j=1}^{K} \text{tr} \left( T_j T_j^H \right) - P_1^{DL} \right) = 0 \tag{40}
\]

\[
\alpha_l \left( \text{tr} \left( Z_l \left( K_{l-1} A_{DL} K_{l-1}^H + C_{l-1}^{DL} \right) Z_l^H \right) - P_l^{DL} \right) = 0 \tag{41}
\]

\[
\alpha_1 \geq 0, \quad \sum_{j=1}^{L} \text{tr} \left( T_j T_j^H \right) \leq P_1^{DL} \tag{42}
\]

\[
\alpha_l \geq 0, \quad \text{tr} \left( Z_l \left( K_{l-1} A_{DL} Z_{l-1} + C_{l-1}^{DL} \right) Z_l^H \right) \leq P_l^{DL}. \tag{43}
\]

In (38), \( X_k^{(c)} \) and \( Y_k^{(c)} \) are defined as

\[
X_k^{(c)} = \left( \sum_{m=1}^{L-c} H^H_{m} Z_{L-m+2} + C_{L-m+2} \right) I_{N_{L-c+1}}, \quad \text{otherwise } k = c \tag{44}
\]

\[
Y_k^{(c)} = \left( \sum_{m=1}^{L-k} H^H_{m} Z_{L-m+1} + C_{L-m+1} \right) I_{N_{L-k+1}}, \quad \text{otherwise } k = c + 1 \tag{45}
\]

**Lemma 2.** For any solutions satisfying the KKT conditions (37)-(43), the Lagrange multipliers are

\[
\alpha_L = \sum_{k=1}^{K} \text{tr} \left( D_k D_k^H \right) \tag{46}
\]

\[
\alpha_{L-1} = \frac{1}{P_{DL}^{UL}} \text{tr} \left( H_L^H \left( \sum_{i=1}^{K} G_i D_i^H D_i G_i^H + \alpha L I_{M_i} \right) Z_L \right) \tag{47}
\]

\[
\alpha_{L-1} = \frac{1}{P_{DL}^{UL}} \text{tr} \left( H_L^H \left( \sum_{i=1}^{K} G_i D_i^H D_i G_i^H + \alpha L I_{M_i} \right) Z_L \right) \tag{47}
\]

\[
\alpha_{L-1} = \frac{1}{P_{DL}^{UL}} \text{tr} \left( H_L^H \left( \sum_{i=1}^{K} G_i D_i^H D_i G_i^H + \alpha L I_{M_i} \right) Z_L \right) \tag{47}
\]

\[
\alpha_{L-1} = \frac{1}{P_{DL}^{UL}} \text{tr} \left( H_L^H \left( \sum_{i=1}^{K} G_i D_i^H D_i G_i^H + \alpha L I_{M_i} \right) Z_L \right) \tag{47}
\]

\[
\alpha_{L-1} = \frac{1}{P_{DL}^{UL}} \text{tr} \left( H_L^H \left( \sum_{i=1}^{K} G_i D_i^H D_i G_i^H + \alpha L I_{M_i} \right) Z_L \right) \tag{47}
\]
Proof: Similar to the proof of Lemma 1, Lemma 2 can also be proved easily.

C. Sum-MSE Uplink-Downlink Duality

Theorem 1. Assume that the uplink transceiver matrices, \( \{F_i\}_{i=1}^{K} \), \( \{B_i\}_{i=1}^{K} \), \( \{W_i\}_{i=1}^{K} \) satisfy the uplink KKT conditions (26)-(32). Let \( T_j = \sqrt{1/\lambda_j} W_j^H \), \( D_j = \sqrt{\lambda_j} B_j^H \), \( Z_i = \sqrt{\lambda_i} L_{-i+2} / L_{-l+2} F_{i}^{DL} \), \( l = 2, \ldots, L \). Then, if the power constraint of the \( l \)-th node of the downlink channel is swapped with the power constraint of the \( (L-l+1) \)-th node of the uplink channel, i.e., \( P_{DL}^l = P_{UL}^{L-l+1} \), \( l = 1, \ldots, L \), sum-MSE achieved by \( \{F_i\}_{i=1}^{K} \), \( \{B_i\}_{i=1}^{K} \), \( \{W_i\}_{i=1}^{K} \) can also be achieved by the downlink transceiver matrices, \( \{Z_i\}_{i=1}^{K} \), \( \{T_j\}_{j=1}^{K} \), \( \{D_j\}_{j=1}^{K} \), which satisfy the KKT conditions (37)-(43). Conversely, assume that the downlink transceiver matrices \( \{Z_i\}_{i=1}^{K} \), \( \{T_j\}_{j=1}^{K} \), \( \{D_j\}_{j=1}^{K} \) satisfy the KKT conditions (37)-(43). Let \( B_j = \sqrt{1/\alpha_j} D_j^H \), \( W_j = \sqrt{\alpha_j} T_j^H \) and \( F_{L-l+2} = \sqrt{\alpha_l/\alpha_l-1} Z_l^H \), \( l = 2, \ldots, L \). Then, if the power constraint of the \( l \)-th node of the uplink channel is swapped with the power constraint of the \( (L-l+1) \)-th node of the downlink channel, i.e., \( P_{UL}^l = P_{DL}^{L-l+1} \), \( l = 1, \ldots, L \), the sum-MSE achieved by \( \{Z_i\}_{i=1}^{K} \), \( \{T_j\}_{j=1}^{K} \), \( \{D_j\}_{j=1}^{K} \) can also be achieved by the uplink transceiver matrices \( \{F_i\}_{i=1}^{K} \), \( \{B_i\}_{i=1}^{K} \), \( \{W_i\}_{i=1}^{K} \), which satisfy the uplink KKT conditions (26)-(32).

Proof: See Appendix B in [10].

Theorem 1 shows that sum-MSE achieved by a transceiver design that satisfies the KKT conditions of an uplink optimization problem, can also be achieved by a transceiver design that satisfies the KKT conditions of a downlink optimization problem, and vice versa. Therefore, the downlink transceiver optimization problems can be solved through solving an equivalent uplink problem, and vice versa. Since the uplink and downlink optimization problems are non-convex, the KKT conditions are only necessary for local minimums in both channels. And by Theorem 1, every possible local minimum (satisfying the KKT conditions) of the uplink sum-MSE corresponds to a same local minimum in the downlink.

IV. Numerical Examples

In this section, we simulate five-hop multiuser MIMO relay systems. For simplicity, we assume all users have the same number of antennas (i.e., \( M_i = M \), \( i = 1, \ldots, K \)) and all relay nodes and the destination node in the uplink have the same number of antennas (i.e., \( N_i = N \), \( i = 1, \ldots, L \)). We set \( P_{UL}^l = P_{DL}^l = 20\text{dB} \) and assume that \( P_{DL}^l = P_{UL}^{L-l+1} = P \), \( l = 2, \ldots, L \). All simulation results are averaged over 1000 channel realizations. We use the iterative algorithm in [11] to design the optimal uplink transceivers \( \{F_i\}_{i=1}^{K} \), \( \{B_i\}_{i=1}^{K} \), \( \{W_i\}_{i=1}^{K} \) and use the proposed duality result to obtain the optimal downlink transceivers \( \{Z_i\}_{i=1}^{K} \), \( \{T_j\}_{j=1}^{K} \), \( \{D_j\}_{j=1}^{K} \). Fig. 3 shows the MSE performance of the uplink and downlink systems versus \( P \) with \( K = 3, M = 2 \), and \( N = 10 \). It can be seen from Figs. 3 that the curves overlap, indicating that both the uplink and downlink systems achieve the same sum-MSE.

V. Conclusion

We have established the uplink-downlink sum-MSE duality in a multi-hop AF MIMO relay system, which is a generalization of several sum-MSE dualities. By analyzing the KKT conditions of the uplink and downlink minimum sum-MSE transceiver optimization problems, it is shown that both the uplink and the downlink systems share the same achievable sum-MSE region.
