Abstract—In this paper, we investigate the transceiver design for an amplify-and-forward interference multiple-input multiple-output (MIMO) relay communication system. The minimum mean-squared error (MMSE) of the signal waveform estimation is chosen as the design criterion to optimize the source, relay, and receiver matrices for interference suppression. An iterative algorithm is proposed to solve the nonconvex source, relay, and receiver optimization problem. Simulation results demonstrate that the proposed algorithm outperforms the existing technique in terms of both MSE and bit-error-rate.

Index Terms—Interference channel, MIMO relay, MSE.

I. INTRODUCTION

Relay aided multiple-input multiple-output (MIMO) communication technology has attracted great research interest recently [1]-[2]. By incorporating relay nodes in a MIMO system, the network coverage and reliability can be significantly improved. In a MIMO relay system, communication between source nodes and destination nodes can be assisted by single or multiple relays equipped with multiple antennas. The relays can either decode-and-forward (DF) or amplify-and-forward (AF) the received signals [3]. In the AF scheme, the received signals are simply amplified (including a possible linear transformation) through the relay precoding matrices before being forwarded to the destination nodes. Therefore, in general the AF strategy has lower complexity and shorter processing delay than the DF strategy.

For single-user two-hop MIMO communication systems with a single relay node, the optimal source and relay precoding matrices have been developed in [4]. For a single-user two-hop MIMO relay system with multiple parallel relay nodes, the design of relay precoding matrices has been studied in [5]. Recent progress on the optimization of AF MIMO relay systems has been summarized in the tutorial of [2].

For MIMO interference channel, the idea of interference alignment (IA) [6] was developed for interference suppression by arranging desired signal and interference into appropriated signal space. The idea of IA has been applied in interference MIMO relay system in [7]-[8]. However, there is still no general solution for IA as a number of conditions must be met. One main reason is that the number of dimensions required for IA is very large and it depends on the number of independent fading channels. This leads to high computational complexity and infeasibility in practical systems. In [9], an iterative algorithm has been proposed to optimize the source beamforming vector and the relay precoding matrices to maximize the signal-to-interference-noise (SINR) at the destination nodes.

In this paper, we investigate the transceiver design for an AF interference MIMO relay communication system where multiple source nodes transmit information simultaneously to the destination nodes with the aid of multiple relay nodes, and each node is equipped with multiple antennas. We aim at optimizing the source, relay, and receiver matrices to suppress the interference and minimize the mean-squared error (MSE) of the signal waveform estimation at the destination nodes, subjecting to transmission power conditions at source and relay nodes. Since the original optimization problem is nonconvex with matrix variables, we propose an iterative algorithm. In each iteration of the proposed algorithm, we first optimize all relay matrices based on the source and receiver matrices from the previous iteration. Then we optimize all source matrices using the relay matrices in this iteration and the receiver matrices from the previous iteration. Finally, the receiver matrices are updated. Simulation results demonstrate that the proposed algorithm outperforms the existing technique in terms of both MSE and bit-error-rate.

Throughout this paper, scalars are denoted with lower or upper case normal letters, vectors are denoted with bold-faced lower case letters, and matrices are denoted with bold-faced upper case letters. Superscripts $T$, $H$, and $-1$ denote transpose, conjugate transpose and inverse, respectively. $tr(\cdot)$ stands for the trace of a matrix, $vec(\cdot)$ stacks columns of a matrix on top of each other into a single vector, $bd(\cdot)$ denotes a block-diagonal matrix, $\otimes$ represents the Kronecker product, $E[\cdot]$ denotes the statistical expectation, and $I_n$ stands for the $n \times n$ identity matrix.

II. SYSTEM MODEL AND PROBLEM FORMULATION

We consider a two-hop interference MIMO relay communication system where $K$ source-destination pairs communicate simultaneously with the aid of a network of $L$ distributed relay nodes as shown in Fig.1. Similar to [9], we ignore the direct links between source and destination nodes as they undergo much larger path attenuation compared with the links via relays. The $k$th source node and the $k$th destination node are
Fig. 1: Block diagram of an interference MIMO relay system.

equipped with \( N_{sk} \) and \( N_{dk} \) antennas, respectively, and the number of antennas at the \( l \)th relay node is \( N_{rl} \).

Using half duplex relay nodes, the communication between source and destination pairs is completed in two time slots. At the first time slot, each source node transmits an \( N_{sk} \times 1 \) signal vector
\[
x_{sk} = B_k s_k, \quad k = 1, \ldots, K
\]
to the relay nodes, where \( s_k \) is the \( d \times 1 \) information-carrying symbol vector and \( B_k \) is the \( N_{sk} \times d \) source precoding matrix. The received signal vector at the \( l \)th relay node is given by
\[
y_{rl} = \sum_{k=1}^{K} H_{lk} x_{sk} + v_{rl}, \quad l = 1, \ldots, L
\]
where \( H_{lk} \) is the \( N_{rl} \times N_{sk} \) MIMO channel matrix between the \( k \)th source node and the \( l \)th relay node and \( v_{rl} \) is the \( N_{rl} \times 1 \) additive white Gaussian noise (AWGN) vector at the \( l \)th relay node with zero mean and covariance matrix \( \mathbb{E} [v_{rl} v_{rl}^H] = \sigma^2_{dl} I_{N_{rl}}, l = 1, \ldots, L \).

The received signal vector at the \( l \)th relay node is amplified with the \( N_{rl} \times N_{rl} \) precoding matrix \( F_l \) as
\[
x_{rl} = F_l y_{rl}, \quad l = 1, \ldots, L
\]
The precoded signal vector \( x_{rl} \) is forwarded to the destination nodes. The received signal vector at the \( k \)th destination node is given by
\[
y_{dk} = \sum_{l=1}^{L} G_{kl} F_l y_{rl} + v_{dk}, \quad k = 1, \ldots, K
\]
where \( G_{kl} \) is the \( N_{dk} \times N_{rl} \) MIMO channel matrix between the \( l \)th relay node and the \( k \)th destination node and \( v_{dk} \) is the \( N_{dk} \times 1 \) AWGN vector at the \( k \)th destination node with zero mean and covariance matrix \( \mathbb{E} [v_{dk} v_{dk}^H] = \sigma^2_{dk} I_{N_{dk}}, k = 1, \ldots, K \).

Due to their simplicity, linear receivers are used at the destination nodes to retrieve the transmitted signal. Thus, the estimated signal vector at the \( k \)th destination node can be written as
\[
\hat{s}_k = W_k^H y_{dk}, \quad k = 1, \ldots, K
\]
where \( W_k \) is the \( N_{dk} \times d \) receiver weight matrix. From (1)-(5),

we have
\[
\hat{s}_k = W_k^H \left( \sum_{l=1}^{L} G_{kl} F_l \sum_{m=1}^{K} H_{lm} B_m s_m + \nu_{dk} \right)
\]
\[
= W_k^H \sum_{l=1}^{L} G_{kl} F_l H_{lk} B_k s_k
\]
desired signal
\[
+ W_k^H \sum_{l=1}^{L} G_{kl} F_l v_{rl} + \nu_{dk}
\]
interference plus noise

where \( \nu_{dk} \triangleq \sum_{l=1}^{L} G_{kl} F_l v_{rl} + \nu_{dk} \) is the total noise at the \( k \)th receiver.

From (1) and (3), the transmission power constraints at the source and relay nodes can be written as
\[
tr(B_k B_k^H) \leq P_{sk}, \quad k = 1, \ldots, K
\]
\[
tr(F_l F_l^H) \leq P_{rl}, \quad l = 1, \ldots, L
\]
where \( P_{sk} \) and \( P_{rl} \) denote the power budget at the \( k \)th source node and the \( l \)th relay node, respectively, and \( E[y_{rl} y_{rl}^H] = \sum_{m=1}^{K} H_{lm} B_m B_m^H H_{lm} + \sigma^2_{rl} I_{N_{rl}} \) is the covariance matrix of the received signal vector at the \( l \)th relay node.

In this paper, we aim at optimizing the source precoding matrices \( \{B_k\} \triangleq \{B_k, k = 1, \ldots, K\} \), the relay precoding matrices \( \{F_l\} \triangleq \{F_l, l = 1, \ldots, L\} \), and the receiver weight matrices \( \{W_k\} \triangleq \{W_k, k = 1, \ldots, K\} \), to minimize the sum-MSE of the signal waveform estimation at the destination nodes under transmission power constraints at the source and relay nodes. We would like to mention that minimal MSE (MMSE) is a sensible design criterion based on the links of MSE to other performance measures in MIMO systems such as mutual information and SINR [4, 10].

From (7), the MSE of the \( k \)th source-destination pair can be calculated as
\[
MSE_k = tr \left( E \left[ (\hat{s}_k - s_k)(\hat{s}_k - s_k)^H \right] \right)
\]
\[
= tr \left( (W_k^H \bar{H}_k - I_d)(W_k^H \bar{H}_k - I_d)^H \right)
\]
\[
+ W_k^H C_k W_k + W_k^H \Xi_k W_k^H, \quad k = 1, \ldots, K
\]
where \( \bar{H}_k \) is the equivalent MIMO channel matrix of the \( k \)th source-destination pair, \( C_k = E[v_{dk} v_{dk}^H] \) and \( \Xi_k \) are the covariance matrices of the equivalent noise and the interference at the \( k \)th pair, respectively. They are given respectively as
\[
\bar{H}_k = \sum_{l=1}^{L} G_{kl} F_l \bar{H}_{lk}, \quad k = 1, \ldots, K
\]
\[
C_k = E \left[ \left( \sum_{l=1}^{L} G_{kl} F_l v_{rl} + v_{dk} \right) \left( \sum_{l=1}^{L} G_{kl} F_l v_{rl} + v_{dk} \right)^H \right]
\]
\[
= \sum_{l=1}^{L} \sigma^2_{dl} G_{kl} F_l^H G_{kl} + \sigma^2_{dk} I_{N_{dk}}, \quad k = 1, \ldots, K
\]
the SMSE (15) can be represented as a function of $f_l = \text{vec}(F_l)$, $l = 1, \cdots, L$, as

$$\text{SMSE} = \sum_{k=1}^{K} \left[ \left( \sum_{l=1}^{L} O_{kl} f_l - \text{vec}(I_d) \right)^H \left( \sum_{l=1}^{L} O_{kl} f_l - \text{vec}(I_d) \right) + tr H^H Q_k f_l + \sum_{l=1}^{L} \sum_{n=1}^{L} f_n^H (\Xi^H_{k,l,n} \otimes G_n^H \Xi_{kl}) f_l \right] + t_1 \tag{19}$$

where $t_1 \equiv \sum_{k=1}^{K} \sigma_{cl}^2 tr(W_{kl}^H W_k)$ is independent of $f_l$, $l = 1, \cdots, L$, and for $k = 1, \cdots, K$, $l = 1, \cdots, L$

$$O_{kl} = H_{ik}^H \otimes G_{kl}, \quad Q_{kl} = \sigma_{cl}^2 I_{N_c} \otimes (G_n^H G_{kl}) \tag{20}$$

For $k = 1, \cdots, K$, let us introduce

$$O_k = [O_{k1}, O_{k2}, \cdots, O_{kL}]$$
$$Q_k = bd(Q_{k1}, Q_{k2}, \cdots, Q_{kL})$$
$$U_{k,l} = \Xi^H_{k,l,n} \otimes (G_n^H G_{kl})$$

Then the SMSE function (19) can be written as a function of $f = [f_1^T, f_2^T, \cdots, f_L^T]^T$ as

$$\psi_1(f) = \sum_{k=1}^{K} \left[ \left( O_k f - \text{vec}(I_d) \right)^H \left( O_k f - \text{vec}(I_d) \right) + f^H Q_k f + f^H U_k f \right] + t_1 \tag{21}$$

By introducing

$$D_l = \left( \sum_{m=1}^{K} H_{lm} B_m D_{ml}^H \sigma_{cl}^2 I_{N_c} \right) \otimes I_{N_{rl}}, \quad l = 1, \cdots, L$$

and $D_l = bd(D_{l1}, D_{l2}, \cdots, D_{lL})$, where $D_l = D_l^T$ and $D_{lj} = 0, l \neq j$, the relay transmit power constraint in (9) can be rewritten as

$$f^H D_l f \leq P_{rl}, \quad l = 1, \cdots, L \tag{22}$$

From (21) and (22), the relay matrices optimization problem can be written as

$$\min_{f} \psi_1(f) \tag{23}$$
$$\text{s.t.} \quad f^H D_l f \leq P_{rl}, \quad l = 1, \cdots, L \tag{24}$$

The problem (23)-(24) is a quadratically constrained quadratic programming (QCQP) problem [13], which is a convex optimization problem and can be efficiently solved by the interior-point method [13]. The problem (23)-(24) can be solved by the CVX MATLAB toolbox for disciplined convex programming [14].
With given receiver matrices \( \{W_k\} \) and relay matrices \( \{F_l\} \), the sum-MSE can be rewritten as a function of \( \{B_k\} \) as

\[
\text{SMSE} = \sum_{k=1}^{K} \left( \sum_{i=1}^{L} \bar{G}_{kl} F_l H_{lk} B_k - I_d \right) \left( \sum_{i=1}^{L} \bar{G}_{kl} F_l H_{lk} B_k - I_d \right)^H + \sum_{l=1}^{L} \sum_{n=1}^{K} \|H_{nm} B_m F_l H_{lm} F_l H_{lk} G_{ln} G_{lm} G_{mk} F_l H_{lk} \| + t_2
\]

(25)

where \( t_2 \triangleq \sum_{k=1}^{K} \text{tr}(W_k^H G_k W_k) \) can be ignored in the optimization process as it is independent of \( \{B_k\} \).

Using the identities in (16)-(18), the SMSE function in (25) can be written as

\[
\text{SMSE} = \sum_{k=1}^{K} \left( \text{tr}(S_k b_k - vec(I_d))^H (S_k b_k - vec(I_d)) \right) + \sum_{l=1}^{L} b_m^H \left( I_d \otimes \sum_{i=1}^{L} \sum_{l=1}^{L} H_{nm}^H F_l H_{nm} G_{km} G_{km} F_l H_{nm} \right) b_m + t_2
\]

(26)

where for \( k = 1, \ldots, K \)

\[
S_k \triangleq I_d \otimes \sum_{i=1}^{L} G_{kl} F_l H_{lk}
\]

\[
T_k \triangleq I_d \otimes \sum_{i=1}^{L} \sum_{l=1}^{L} H_{nm}^H F_l H_{nm} G_{mn} G_{mk} F_l H_{lk}.
\]

By introducing \( T \triangleq bd(T_1, T_2, \ldots, T_K) \) and \( S_k \triangleq [S_{k1}, S_{k2}, \ldots, S_{kK}] \), where \( S_{kk} = S_k \) and \( S_{ji} = 0, \ i \neq k \), the SMSE function (26) can be written as a function of \( b = [b_1^T, b_2^T, \ldots, b_K^T]^T \) as

\[
\Phi_1(b) = \sum_{k=1}^{K} \left( S_k b_k - vec(I_d) \right)^H (S_k b_k - vec(I_d)) + b^H T_k b + t_2.
\]

(27)

Let us introduce \( E_{ij} = I_d \otimes (H_{ij}^H F_l^H F_l H_{ij}) \), \( E_i = bd(E_{i1}, E_{i2}, \ldots, E_{iK}) \), \( E_i = bd(E_{i1}, E_{i2}, \ldots, E_{iK}) \), where \( E_{ii} = I_{dN_i} \) and \( E_{ij} = 0, \ i \neq j \). The optimal \( b \) can be obtained by solving the following problem

\[
\min_{b} \ \Phi_1(b)
\]

subject to

\[
\text{s.t.} \quad b^H E_l b \leq P_{sm}, \ m = 1, \ldots, K
\]

\[
\text{s.t.} \quad b^H E_l b \leq P_{rl} - \sigma_{rl}^2 \text{tr}(F_l F_l^H), \ l = 1, \ldots, L.
\]

(28)

(29)

(30)

The problem (28)-(30) is a QCQP problem and can be solved by the CVX MATLAB toolbox [14] for disciplined convex programming.

The steps of applying the proposed iterative algorithm to optimize \( \{B_k\}, \{F_l\} \), and \( \{W_k\} \) are summarized in Table I, where the superscript \((n)\) denotes the variable at the \(n\)th iteration, and \( \varepsilon \) is a small positive number up to which convergence is acceptable. Since all subproblems (11), (23)-(24), and (28)-(30) are convex, the solution to each subproblem is optimal. Thus, the value of the objective function (11) decreases after each iteration. Moreover, the objective function is lower bounded by at least zero. Therefore, the iterative algorithm converges to (at least) a locally optimal solution.

### IV. NUMERICAL EXAMPLES

In this section, we illustrate the performance of the proposed algorithm through numerical simulations. All channel matrices have independent and identically distributed (i.i.d.) complex Gaussian entries with zero-mean and unit variance. The noises are i.i.d. Gaussian with zero mean and unit variance. The QPSK constellations are used to modulate the source symbols. For the sake of simplicity, we assume that all nodes have three antennas, i.e., \( N_{sk} = N_{dk} = N_{rl} = 3, k = 1, \ldots, K, l = 1, \ldots, L \). All source nodes have the same power budget as \( P_{sk} = P_s = 15\text{dB} \), \( k = 1, \ldots, K \), and all relay nodes have the same power budget as \( P_{rl} = P_r = l = 1, \ldots, L \). For all simulation examples, there are \( K = 3 \) source-destination pairs, and the simulation results are averaged over \( 10^5 \) independent channel realizations. Unless explicitly mentioned, we assume that there are \( L = 5 \) relay nodes in the interference MIMO relay system. As a benchmark, we compare the performance of the proposed algorithm with the naive AF algorithm with the source and relay precoding matrices are scaled identity matrices.

In the first example, we study the performance of the proposed algorithm at different number of iterations. Fig. 2 shows the BER performance of the proposed algorithm at different number of iterations for the first source-destination pair \((k = 1)\). It can be seen from Fig. 2 that the proposed algorithm yields a much smaller BER than the naive AF algorithm, since the source and relay precoding matrices are not optimized in the naive AF algorithm. It can also be observed from Fig. 2 that the system BER reduces with increasing number of iterations. During simulations, we observed that after 20 iterations, the decreasing of the SMSE objective function is negligible. Thus, we suggest that only 20 iterations are needed to achieve good performance.

For this example, the BER of each source-destination pair versus \( P \) at 10 iterations is shown in Fig. 3. It can be seen

[Table I]

</table>

that all three source-destination pairs achieve almost identical BER, indicating that the proposed algorithm is fair to all links.

In the second example, we study the performance of the proposed algorithm with different number of relay nodes. Fig. 4 shows the BER performance of the proposed algorithm at 10 iterations with $L = 5$ and $L = 10$. It can be seen that by increasing the number of relay nodes, the system spatial diversity is increased, and thus, a better BER performance is achieved. In particular, we observe that a 10dB gain is obtained at the BER of $10^{-3}$ by increasing $L$ from 5 to 10.

V. CONCLUSION

We have investigated transceiver design for interference MIMO relay systems based on the MMSE criterion. An iterative algorithm has been developed to jointly optimize the source, relay, and receiver matrices under power constrains at each source node and relay node. Numerical simulation results show that this algorithm converges quickly after a few iterations and has better BER performance than the existing technique.
